Feick, S., Siebert, S. and Döll, P. (2005): A Digital Global Map of Artificially Drained Agricultural Areas. *Frankfurt Hydrology Paper 04*, Institute of Physical Geography, Frankfurt University, Frankfurt am Main, Germany.

Abstract

Artificial drainage of agricultural land, for example with ditches or drainage tubes, is used to avoid water logging and to manage high groundwater tables. Among other things it influences the nutrient balances by increasing leaching losses and by decreasing denitrification. To simulate terrestrial transport of nitrogen on a global scale, a digital global map of artificially drained agricultural areas was developed. The map depicts the percentage of each 5' by 5' grid cell that is equipped for artificial drainage. Information on artificial drainage in countries or sub-national units mainly derived by information from international data sets. Distribution to grid cells was based, for most countries, on the "Global Croplands Dataset" of Ramankutty et al. (1998) and the "Digital Global Map of Irrigation Areas" of Siebert et al. (2005). For some European countries CORINE land cover dataset was used instead of the both datasets mentioned above. Maps with outlines of artificially drained areas were available for 6 countries. The global drainage area on the map is 167 Mio hectares. For only 11 out of the 116 countries with information on artificial drainage areas, subnational information could be taken into account. Due to this coarse spatial resolution of the data sources, we recommended to use the map of artificially drained areas only for continental to global scale assessments. This documentation describes the dataset, the data sources and the map generation, and it discusses the data uncertainty.

1 Introduction

In general, artificial drainage¹ of agricultural land is used to avoid water logging and to manage high groundwater tables. In arid regions, drainage of irrigated lands avoids salinization and is thus, for many soils, a prerequisite for sustainable land use. In humid regions, drainage helps to extend the period in which the field can be entered with heavy machines. Artificial drainage decreases the average water content of the subsoil and accelerates the transport of water through the soil. Therefore, it influences nutrient transport by increasing leaching losses and by decreasing denitrification.

Although multiple impacts of artificial drainage exist there is no global map of areas with artificially drained agricultural areas. This required us to use heterogeneous information from national and international sources to produce a first indicative map. The resulting digital global map of artificially drained agricultural areas (or “areas with improved drainage”) is a raster map with a resolution of 5 min longitude by 5 min latitude. For the whole land area of the globe (except Antarctica), the data set provides the fraction of each 5 min by 5 min cell area that is equipped for improved drainage. The map is mainly based on:

- national statistics from international data sources (FAO, ICID, CEMAGREF etc.)
- the “Global Croplands Dataset” (Ramankutty et al., 1998) and
- the “Digital Global Map of Irrigation Areas” (Siebert et al., 2005).

Due to the spatial resolution of the data sources (mainly on country level) we recommend to use the map of artificially drained areas only for continental to global scale assessments. The map will be applied, for example, to simulate terrestrial transport of nitrogen with the model WaterGAP-N (Siebert, 2005) which is a further development of the global model of water availability and water use WaterGAP 2.1 (Alcamo et al., 2003) or to simulate accelerated interflow on drained agricultural lands with the hydrological model WGHM (Döll et al., 2003) of WaterGAP.

This documentation comprises a description of the data set, which includes information on the data sources of the map (Chapter 2). In Chapter 3 the map generation is characterised and in Chapter 4, a short discussion of the results and the uncertainties of the data set follows. In Appendix A, detailed tables with the data sources and the references of the data sources per country

¹ In this document “drainage” means artificial/improved drainage of agricultural areas (e.g. areas equipped with ditches or drainage tubes)

are provided as well as the value of the artificial drainage area per country and sub-national unit. In Appendix B, the global map of artificially drained agricultural areas and a map with the spatial units of the artificial drainage map for which statistical information on drained areas were available are shown. Moreover, zooms to North and Central America and to Europe and North Africa are provided in Appendix B.

2 Description of Data Set

The digital global map of artificially drained agricultural areas (or “areas with improved drainage”) is a raster map with a resolution of 5 min by 5 min. For the whole land area of the globe (except Antarctica), the data set provides the fraction of each 5 min by 5 min cell area that was equipped for improved drainage. The map is shown in Appendix B. In the following, the artificially drained agricultural areas will be called "drained areas". The global drainage area on the map is 167 Mio hectares. Drainage areas equipped for flood control measurements are not included in the map (if distinguishable from the data).

2.1 Data Format

Two raster maps are available (in ASCII format). The first map shows the drained area in hectares per 5' by 5' grid cell. The other raster map provides the percentage of each 5' by 5' cell area that is drained, the so-called drainage density. The document and the maps are available at: http://www.geo.unifrankfurt.de/ipg/ag/dl/forschung/Global_Drainage_Map/index.html.

2.2 Data Sources

The main sources of the global map of artificially drained areas are international data sets from FAO (FAO AQUASTAT, 1994, 2003, 2004), ICID (2005) and CEMAGREF (2005), which are based on various data sources. These datasets often distinguish between drainage in irrigation areas and drainage in rainfed areas. On the basis of the “Global Croplands Dataset” (Ramankutty et al., 1998) and the “Digital Global Map of Irrigation Areas” (Siebert et al., 2005) three 5' grids were generated: 1. Total cropland area, 2. Rainfed cropland area, 3. Irrigated cropland area. Within a country or sub-national unit the drainage area was distributed according to the percentage of the grid cell covered by “Total Cropland” or “Rainfed Cropland” and “Irrigated Cropland” depending on data availability. For 105 countries the drainage area was assigned to the agricultural area in the respective country or the respective sub-national units of the country. For 5 coun-

tries (Algeria, Austria, Romania, Switzerland and Zambia) maps with outlines of improved drainage areas were available from Framji et al. (1981-83), and used to locate drainage areas. For Germany a map with outlines of the tile-drainage density in per cent of the arable land was available (Röpke et al., 2004) and for Russia the shapefile “Land Resources of Russia” (IIASA, 2002) which includes artificially drained areas, was used. In European countries with a high percentage of drained pasture land and/or not enough cropland area to assign the given drainage area, the CORINE land cover data sets from 1990 (Switzerland) and 2000 (Austria, Estonia, Finland, Germany, Latvia, Netherlands and Romania) which including pasture land were used to locate the drainage area. For the 12 countries shown in Table 1 sub-national statistical information were found. For 134 countries no data values about artificial drainage areas were available.

Table 1: Countries with available sub-national statistical information of improved drainage area

Country	Administrative Unit
Afghanistan	Province
Albania	District
Algeria	Province
Australia	State/Territory
China	Province
Egypt	Governorate/Region
Estonia	County
France	Region
Germany	Western Germany, Eastern Germany
Latvia	County
Pakistan	Province
USA	State

For every country, the most recent information or the information with the highest spatial resolution was used to generate the global map of artificially drained agricultural areas. In Table A1 of the appendix used data source(s) and further (not used) data source(s) of drainage areas are listed for each country. In Table A2, the respective references are given.

3 Map Generation

The generation of the digital map of artificially drained areas included a number of steps that depended on the type of data that was available for the respective country. The four main calculation routes are depicted in Fig. 1 and shortly characterized below:

- a) For 105 countries the statistical drainage area was assigned to the cropland area in the respective country or the respective sub-national units of the country. Depending on the available data the drainage area assigned either to the “total cropland area” or the “rainfed cropland area” and the “irrigated cropland area”. The total cropland area and the rainfed area are calculated on the basis of the “Global Croplands Dataset” (Ramankutty et al., 1998) and the “Digital Global Map of Irrigation Areas” (Siebert et al., 2005) as shown in Figure 1. For countries with information about the amount of drainage area in irrigated and/or rainfed lands the drainage area was assigned to these areas. For countries without separate information about the amount of the drainage area in irrigated and/or rainfed lands, the drainage area was assigned to the total cropland area (= irrigated + rainfed).
- b) The drainage area of the four countries Estonia, Finland, Latvia and the Netherlands was assigned to the total area of 5 appropriate land cover classes of the CORINE 2000 dataset.
- c) Maps with outlines of drainage areas were digitized for 6 countries. For 4 countries (Austria, Germany, Romania and Switzerland) out of these 6 the drainage area was assigned to the total area of 5 appropriate land cover classes of the CORINE 2000 (for Switzerland the CORINE 1990) dataset inside the digitized outlines. The drainage area of the other 2 countries was assigned to the total cropland area (Algeria) and the irrigated area (Zambia) respectively.
- d) Artificially drained areas in Russia are shown separately in the shapefile “Land Resources of Russia” (IIASA, 2002). The statistical drainage area for Russia (Source: FAO AQUASTAT, 2004) was assigned to the extracted drainage area from the IIASA shapefile.

The procedure of digitizing maps with outlines of drained areas is described in Chapter 3.1. For some countries a special assignment of the statistical drainage area to the spatial units was necessary. These special cases are explained in Chapter 3.2. The drainage area per country is listed in Table A3. For the countries with sub-national information, Tables A4 to A15 provide the drainage area per administrative unit. No Data values in the map as well as in Tables A3 to A15 mean no information was available or found.

Coefficient F = Drainage Area _(Spatial Unit) / Total Cropland Area _(in digitized areas per Spatial Unit)

¹⁷⁾ Coefficient G = Drainage Area _(Statistics) / Drainage Area _(IIASA)

3.1 Digitization of maps with outlines of drained areas

In Framji et al. (1981-83) maps with outlines of drained areas are available for 5 countries (Algeria, Austria, Romania, Switzerland and Zambia). For Germany a map with outlines of the tile-drainage density in per cent of the arable land was available (Röpke et al., 2004). These maps were digitised using the GIS software ArcView 3.2. First, the maps were scanned with a resolution of 600 dpi. Then the scanned maps were georeferenced by the country-border lines because no map has a (geographic) coordinate system. The georeferencing was done with the GIS ArcView 3.2. This step was followed by a manual digitization of the drainage areas on the screen using the mouse cursor.

3.2 Special assignments of statistical drainage area to the respective spatial units

In some countries a special assignment of the drainage data to the spatial units, which is not described in Fig. 1, was necessary. These cases are listed below with a short description of the respective assignment method:

Algeria

Sub-national units listed in the CEMAGREF (2005) database are not available in the ESRI shapefile datasets (1998, 2004) of administrative units. Therefore, the country value for drainage area was taken and assigned to cropland area within digitised outlines.

China

Drainage area for each province (Agricultural Yearbook, 1995) and the value for total drainage area in irrigated lands from FAO (2004) were taken into account. To determine drained irrigated area per province, the drained irrigated area of China as a fraction of the drained area of China was multiplied by the drainage area per province. In one province (Heilongjiang), the thus computed drained irrigated area is higher than the total irrigated area from Siebert et al. (2005). The surplus drainage area:

$$\text{Surplus drainage area} = [(\text{Total Drainage Area}_{(\text{in irrigated lands})} / \sum \text{Drainage Area}_{(\text{Province})}) * \\ \text{Drainage Area}_{(\text{Heilongjiang})}] - \text{Irrigation Area}_{(\text{Heilongjiang})}$$

was distributed to the remaining provinces with drainage area and irrigation area.

To determine the drainage area in rainfed lands per province, the drained rainfed area of China as a fraction of the total drained area of China was multiplied by the drainage area per province.

Egypt

In Egypt all drainage area is placed within irrigated lands (FAO, 2004). For the “West Delta” region total irrigation area is lower than the area for drained irrigated areas. Therefore, the surplus drainage area was assigned to rainfed area in this region (Annex A, Tab. A9).

Estonia

Drainage area per county was assigned to the area of 5 land cover classes of the CORINE (2000) dataset (Fig. 1). In one county (Hiiumaa) CORINE (2000) area is lower than necessary. Therefore, drainage area for Estonia in the map is smaller than the value from the FAO (1998) statistic.

France

In one région (Limousin) total crop area is lower than drainage area from statistic (Agreste, 1991). Although drainage area was distributed to all of the irrigation and rainfed area within this région, the computed drainage area for France is smaller than the value from the Agreste (1991) statistic (Annex A, Tab. A1 and A11).

Germany

In Röpke et al. (2004) the outlines of tile-drainage density in per cent of the arable land are shown in a map (based on data from Behrendt et al. 1999). These outlines were digitised and assigned to the area of 5 land cover classes (= total arable land) of the CORINE (2000) dataset. Per cent values from Röpke et al. (2004) then multiplied with arable land per digitised area (= calculated arable land). The total resulting area for Western-Germany and Eastern-Germany is larger than the given drainage areas of Behrendt et al. (1999) for these two parts of Germany. Therefore, one coefficient for Western-Germany and another coefficient for Eastern-Germany had to be calculated:

$$1) \text{ Coefficient}_{(\text{W-Germany})} = \text{Drainage Area}_{(\text{W-Germany})} / \sum \text{Calc. Arable Land}_{(\text{W-Germany})}$$

$$2) \text{ Coefficient}_{(\text{E-Germany})} = \text{Drainage Area}_{(\text{E-Germany})} / \sum \text{Calc. Arable Land}_{(\text{E-Germany})}$$

Finally the coefficients were multiplied with the calculated arable land per digitised area to get the necessary drainage area (s. Fig.1).

Greece

According to Framji et al. (1981-83) 42 % of the 600.000 ha drained land are located within irrigated areas. In the “international drainage database” of CEMAGREF (2005), a drainage area of 600.000 ha is given, too. The cited data source (Field, W.P., 1990) is older than the cited data sources of the ICID (2005) dataset and so the ICID value of 520.000 ha drained area was taken into account. To get a value for drainage area in irrigated and rainfed lands, the 520.000 ha were multiplied by 0.42.

Hungary

The total irrigated area of Hungary (214.039 ha) is smaller than the 320.000 ha drained area in irrigated lands from the CEMAGREF (2005) dataset. The resulting surplus drainage area was assigned to the rainfed part of the total crop area in Hungary.

Japan

It was tried to assign the total drainage area of Japan to irrigated land, because most of the irrigated land in Japan is paddy cultivation, and paddy cultivation and drainage are linked in general (FAO, 1999). However, the irrigated area of Japan (3.129.000 ha) is smaller than the total drainage area (3.660.000 ha). So the resulting surplus drainage area was assigned to rainfed cropland.

Slovenia

The total irrigated area of Slovenia (2.802 ha) is smaller than the 8.000 ha drained area in irrigated lands from the CEMAGREF (2005) dataset. The resulting surplus drainage area was assigned to rainfed cropland.

Suriname

According to CEMAGREF (2005), all of Suriname’s drainage area (51.180 ha) is in areas equipped for irrigation. But the irrigated area of Suriname is only 50.069 ha. The resulting surplus drainage area was assigned to rainfed cropland.

USA

Based on the drainage values from the US Department of Agriculture (USDA, 1987) and CEMAGREF (2005), the assignment of drained areas per state was realized. USDA (1987) provides values for 23 states (Sum: 41.356.189 ha) and a value for the whole United States (44.384.620 ha). The difference between the two values was distributed to the other 28 states proportional to the cropland area per state (only 28 remainder states because in Guantanamo Bay no cropland area exists). In the CEMAGREF (2005) database a value for the United States (47.500.000 ha) is given and split into a part of drainage area in irrigated (5.750.000 ha) and in rainfed (41.750.000 ha) lands. The difference between the value of total drained area in CEMAGREF (2005) and USDA (1987) was distributed to the 23 states given from the USDA (1987) proportional to the amount of existing drainage area.

To split now the drainage area per state into a part located in irrigated areas and a part located in rainfed areas, a federal state was identified to have dominantly irrigated agriculture if:

$$(\text{Irrigation area}_{(\text{State})} / \text{Rainfed area}_{(\text{State})}) > 0.75.$$

In the resulting 10 states (Arizona, California, Colorado, Hawaii, Idaho, Nevada, New Mexico, Oregon, Utah and Wyoming), drained area was completely assigned to irrigated lands. In the remaining 40 states (in the District of Columbia there is no irrigation) the surplus drained irrigated area was distributed. In two states (Washington and Nebraska) irrigation area is too small to contain all of the resulting drainage area. The surplus drainage area was assigned to the irrigated area of the other 38 states.

The per state rainfed part of the drainage area resulted by the following calculation:

$$5) \text{ Drainage Area}_{(\text{rainfed per State})} = \text{Drainage Area}_{(\text{State})} - \text{Drainage Area}_{(\text{irrigated per State})} .$$

4 Discussion and Conclusions

The digital global map of artificially drained agricultural areas shows the percentage of 5' grid cell area with artificial drainage. The quality of the generated global map of artificially drained areas depends mainly on the quality of used base data, in particular on its (low) spatial resolution. For only 11 out of the 116 countries with information on artificial drainage areas sub-national information could be taken into account. For 5 out of the 6 countries with maps of outlines of

artificial drainage areas, data are from the 1960s and 1970s (in Framji et al., 1981-83). In these cases, the mapped drainage area is probably too localized. Furthermore, for many countries different and deviating data sources exist (Table A1). For example, in the CEMAGREF (2005) data set a difference is made between “on farm drainage systems” and “main drainage system only”. For many countries the sum of both values is the drainage value given by ICID (2005). Therefore, if data for a country is available from ICID (2005) and from CEMAGREF (2005) we consider only the values for “on farm drainage systems” from CEMAGREF (2005). Moreover in the FAO datasets and the ICID (2005) dataset no difference is made between drainage facilities for agricultural and construction purposes. Due to this, in humid regions with heavy soils like in the Baltic States the drained area is larger than the cultivated area (FAO, 1997) and the drained area is probably overestimated in the map. Besides, it must be pointed out, that there is no global data-set of pasture areas. Thus, drainage areas could be distributed to pasture lands only in countries with CORINE land cover information which include the land cover class “pasture land” (done for 8 countries), even though in other countries drained pastures exist. That means, that in all other countries except the 8 countries for which CORINE data used, the drainage area maybe distributed (to some extent) to the wrong cells.

The high spatial heterogeneity of the mapped drainage density is misleading, in that it is not due to spatially highly resolved information on drainage areas but on the different cropland areas in each 5' grid cell. The drainage density as defined by the drained area as a ratio of cropland area is assumed to be constant within each country or sub-national unit, respectively. Besides, we could not consider the relation between soil type and drainage necessity as we think that within each grid cell agriculture preferentially takes place on relatively favourable soils which are not necessarily the dominant soils.

In summary, the information provided by the global map of artificially drained areas is rather uncertain. This is mainly due to the quality of the data that served as input to the map. Thus, we recommended using the map of artificially drained areas only for continental to global-scale assessments.
